Office Action Summary

Application No.

10/591,922

Applicant(s)

JALOWIECKI ET AL.

Examiner

MICHAEL ALSIP

Art Unit

2186

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --
Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

- 1) ☒ Responsive to communication(s) filed on 25 March 2011.
- 2a) ☐ This action is **FINAL**. 2b) ☒ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

- 4) ☒ Claim(s) 1-6 and 8-25 is/are pending in the application.
- 4a) Of the above claim(s) _____ is/are withdrawn from consideration.
- 5) ☐ Claim(s) _____ is/are allowed.
- 6) ☒ Claim(s) 1-6 and 8-25 is/are rejected.
- 7) ☐ Claim(s) _____ is/are objected to.
- 8) ☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☐ The drawing(s) filed on _____ is/are: a) ☐ accepted or b) ☐ objected to by the Examiner.
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

- 12) ☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☒ All b) ☐ Some * c) ☐ None of:
1. ☒ Certified copies of the priority documents have been received.
 2. ☐ Certified copies of the priority documents have been received in Application No. _____.
 3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

Attachment(s)

- 1) ☒ Notice of References Cited (PTO-892)
- 2) ☐ Notice of Draftsperson's Patent Drawing Review (PTO-040)
- 3) ☐ Information Disclosure Statement(s) (PTO/SB-08)
Paper No(s)/Mail Date _____
- 4) ☐ Interview Summary (PTO-413)
Paper No(s)/Mail Date _____
- 5) ☐ Notice of Informal Patent Application
- 6) ☐ Other: _____

DETAILED ACTION

Claim Rejections - 35 USC § 103

1. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

2. The factual inquiries set forth in *Graham v. John Deere Co.*, 383 U.S. 1, 148 USPQ 459 (1966), that are applied for establishing a background for determining obviousness under 35 U.S.C. 103(a) are summarized as follows:

1. Determining the scope and contents of the prior art.
2. Ascertaining the differences between the prior art and the claims at issue.
3. Resolving the level of ordinary skill in the pertinent art.
4. Considering objective evidence present in the application indicating obviousness or nonobviousness.

3. **Claims 1-6, 8-10, 12-19 and 24-25** are rejected under 35 U.S.C. 103(a) as being unpatentable over Baddiley (US 4,852,065), and further in view of Anderson et al. (US 2004/0111567).

4. Consider **claim 1**, Baddiley discloses a multi-ported orthogonal data memory for effecting a corner-turning function, where for example data input as a sequence of bit-parallel word-serial data transfers are converted to data output in a bit-serial, word-parallel fashion; the memory being arranged to transfer data words comprising a plurality of data items (fig. 2, abstract, Col. 1 lines 4-30 and Col. 3 lines 20-50, where a data item is considered to be a data word or some portion of a data word.) and

comprising: a plurality of data memory cells arranged in the form of a matrix having rows and columns, and a plurality of groups of memory cells within the matrix, **each group being: i) a subgroup of the total number of memory cells in the matrix, ii) having members of the group located in different rows and in different columns of the matrix, and iii) being** individually addressable to effect transfer of a data word thereto (fig. 2, Col. 3 lines 20-58 and Col. 5 lines 1-10, where a group of memory cells can be each buffer 20 and 21 themselves or a subset of a buffer that spans multiple rows and columns and the word data that is stored in each buffer and thus each group can be used to handle words of 32-bit size or smaller based on preset values and therefore each group is related to data items of a different size. Also, in the case of a 32-bit word, the word itself will be stored in 4 rows and 8 columns because there are only 8 bits per row of the buffer.); and enabling means having dedicated strobe connections to each of the plurality of groups of memory cells and being arranged to enable selected ones of the plurality of groups of memory cells, as determined by the size of the data items being transferred, to read **all of the data items of the data word** present at their inputs **into the selected group of memory cells** or to write **all of the data items of the data word** stored **in the selected group of memory cells** to their outputs in a single transfer operation (Fig. 2 and 3, Col. 3 lines 20-58 and Col. 5 lines 1-10, where each buffer is selected after a determination of the size of the data items is made and the arrangement of the data in the buffer is effected by the word size. Each buffer has dedicated connections for reading out and writing in data words as shown in fig. 2 and 3 and a write or read operation is considered a single transfer operation.).

Baddiley does not explicitly disclose that the claimed single transfer operation occurs in a **single clock cycle**. But Anderson et al. does teach that it is conventional for a multi-port memory devices to be able to read and write data in a single clock cycle (pg. 1 ¶ [0010]) and further that the improved multiport-memory of Anderson can also perform read and write access operations in one clock cycle, this improved multiport-memory can provide a significant reduction in chip area for a given memory storage capacity.

It would have been obvious to one of ordinary skill in the art at the time of the invention for the multi-ported memory of Baddiley to be able to perform read and write operations in one clock cycle, because Anderson et al. teaches that conventional multiport memories can perform read and write accesses to data in one clock cycle (pg. 1 ¶ [0010]) and further because the improved multiport-memory of Anderson can also perform read and write access operations in one clock cycle, this improved multiport-memory can provide a significant reduction in chip area for a given memory storage capacity (pg. 1 ¶'s [0010] and [0011]).

5. Consider **claim 2**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, wherein each of the groups of memory cells is specified according to its use in transferring the data items of the data word to or from the matrix to effect the corner-turning function (Baddiley: Col. 3 lines 20-58, each buffer is designated to either be a write or read buffer).
6. Consider **claim 3**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, wherein the enabling means comprises selection means for

selecting the current size of the data items in the data word and configuring the enabling means to operate with the selected current size of data items (Baddiley: Col. 5 lines 1-10, where the size of the data items in the word is considered the size of the data items together that make up the whole word).

7. Consider **claim 4**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 3**, wherein the number of different groups of memory cells provided within the matrix equals the number of different sizes of data items which can be handled by the memory (Baddiley: Fig. 2, col. 3 lines 20-50 and Col. 5 lines 1-10, where a group of memory cells can be considered any subset of memory cells of a buffer that spans multiple rows and columns and word sizes of 32 bits or lower can be used by the system, therefore since a group is merely defined as spanning multiple rows and columns, the number of groups can be equal to the number of sizes available).

8. Consider **claim 5**, Baddiley in view of Anderson et al. Discloses a memory according to **Claim 3**, wherein each item of the data word being transferred is an integer power-of-two multiple of eight bits (Baddiley: Col. 5 lines 1-10).

9. Consider **claim 6**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, wherein the memory is arranged to operate with different types of data words, each type comprising 64, 32, 16 or 8-bit data items (Baddiley: Col. 5 lines 1-10).

10. Consider **claim 8**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 7**, wherein the enabling means is arranged to enable a selected group upon a set of logic conditions becoming true, the logic conditions being

determined from a current selected row of the matrix and the size of the items being transferred (Baddiley: fig. 2 and 4, Col. 3 lines 20-59 and Col. 5 lines 1-10, where logic conditions include the decoder using the control and address bits to select particular rows or columns in a particular buffer).

11. Consider **claim 9**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, wherein the enabling means comprises a pointer in a shift register (38) for determining which rows of the matrix are to be enabled for taking part in the data transfer of all of the data items of the data word (Baddiley: Fig. 4, Col. 3 lines 50-59, Col. 4 lines 33-37, where register 45 comprises a reference to counter 40 and is used in determining the control and address bits to enable particular rows of the matrix).

12. Consider **claim 10**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 9**, wherein the pointer in the shift register (38) is configured to be operable in a plurality of different modes, each mode corresponding to a possible size of the data item being transferred, the pointer being configured within a single instruction to advance by a predetermined number of bit positions as determined by the current mode thereby indicating which rows of the matrix are to be enabled to facilitate transfer of the whole of the data word to or from the matrix (Baddiley: fig. 4, Col. 3 lines 30-59, col. 4 lines 33-37 and Col. 5 lines 1-10, where register 45 determines word size and address and control bits to indicate rows and columns of a matrix to facilitate transfer of data words).

13. Consider **claim 12**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 9**, further comprising means for converting the current position of

the row pointer in the shift register (38) to one or more row select logic signals (Baddiley: Fig. 4, Col. 3 lines 50-59, Col. 4 lines 33-37, where register 45 comprises a reference to counter 40 and is used in determining the control and address bits to enable particular rows of the matrix).

14. Consider **claim 13**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 12**, further comprising a hard-wired backward propagation network for determining, from the bit position of the pointer and the size of the current data items, the rows of the matrix that are to be enabled for the data transfer (Baddiley: Fig. 4, Col. 3 lines 50-59, Col. 4 lines 33-37, where register 45 comprises a reference to counter 40 and is used in determining the control and address bits to enable particular rows of the matrix, the components of fig. 4 perform the functions claimed to be performed by the hard-wired backward propagation network).

15. Consider **claim 14**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, wherein the enabling means comprises byte column determining means for enabling a specific group of byte column locations of the matrix within a selected word row to be enabled for transferring an item of the data word across a word port of the memory (Baddiley: Fig. 3-4 Col. 4 lines 6-46 and Col. 5 lines 45-62, where register 46 comprises a reference to counter 41 and is used in determining the control and address bits to enable particular columns of the matrix and 43 determines which buffer is being referenced by which register/counter combination).

16. Consider **claim 15**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 14**, wherein the byte column determining means comprises a table

specifying the relationship between the plurality of different groups of memory cells and their respective memory cell locations in the matrix (Baddiley: fig. 3-4, Col. 3-4 lines 29-41 and 59-33 and Col. 5 lines 45-62, where register's 40 and 41 consist of a linear table of bits with indicate a particular row/column for reading or writing information in a particular buffer).

17. Consider **claim 16**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, wherein the enabling means comprises bit column determining means for enabling a specific group of bit column locations of the matrix within a selected word row to be enabled for transferring a bit of an item of the data word across a bit port of the memory (Baddiley: Fig. 3-4 Col. 4 lines 6-46 and Col. 5 lines 45-62, where register 46 comprises a reference to counter 41 and is used in determining the control and address bits to enable particular columns of the matrix and 43 determines which buffer is being referenced by which register/counter combination).

18. Consider **claim 17**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 16**, wherein the bit column determining means comprises a table specifying the relationship between the plurality of different groups of memory cells and their respective memory cell locations in the matrix (Baddiley: fig. 3-4, Col. 3-4 lines 29-41 and 59-33 and Col. 5 lines 45-62, where register's 40 and 41 consist of a linear table of bits with indicate a particular row/column for reading or writing information in a particular buffer).

19. Consider **claim 18**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, wherein the locations of the memory cells of each group form a repeating pattern when viewed as a matrix (Baddiley: fig. 2).
20. Consider **claim 19**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, further comprising a load register (42) arranged to retain temporarily bit-serial word parallel data transferred to and from the matrix of memory cells across a bit port of the memory (Baddiley: Fig. 3 and Col. 4 lines 20-25).
21. Consider **claim 24**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 2**, wherein the enabling means comprises selection means for selecting the current size of the data items in the data word and configuring the enabling means to operate with the selected current size of data items (Baddiley: Col. 5 lines 1-10, where the size of the data items in the word is considered the size of the data items together that make up the whole word).
22. Consider **claim 25**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 3**, wherein the enabling means comprises a pointer in a shift register (38) for determining which rows of the matrix are to be enabled for taking part in the data transfer of all of the data items of the data word (Baddiley: Fig. 4, Col. 3 lines 50-59, Col. 4 lines 33-37, where register 45 comprises a reference to counter 40 and is used in determining the control and address bits to enable particular rows of the matrix).

Claim Rejections - 35 USC § 103

23. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

24. The factual inquiries set forth in *Graham v. John Deere Co.*, 383 U.S. 1, 148 USPQ 459 (1966), that are applied for establishing a background for determining obviousness under 35 U.S.C. 103(a) are summarized as follows:

1. Determining the scope and contents of the prior art.
2. Ascertaining the differences between the prior art and the claims at issue.
3. Resolving the level of ordinary skill in the pertinent art.
4. Considering objective evidence present in the application indicating obviousness or nonobviousness.

25. **Claim 11** is rejected under 35 U.S.C. 103(a) as being unpatentable over Baddiley (US 4,852,065) in view of Anderson et al. (US 2004/0111567) as applied to **claim 9** above, and further in view of Kim et al. (US 6,781,898 B2).

26. Consider **claim 11**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 9**, Baddiley in view of Anderson et al. does not disclose what happens if a faulty row exists in the matrix, however Kim et al. does teach the following claimed features: storing information relating to a faulty row in the matrix and wherein the shifting word pointer register (38) is arranged to be controlled to skip the faulty row in the matrix and instead point to otherwise redundant additional row of the matrix (abstract, Col. 1 lines 40-46 and Col. 2 lines 8-23).

It would have been obvious to one of ordinary skill in the art at the time of the invention to include the teachings of Kim et al. with that of Baddiley and Anderson et al., because Kim teaches that detecting and skipping defective rows in a memory and then using an additional redundant row in its place, doing this improves memory yield and ensures proper operation of the memory (abstract, Col. 1 lines 23-46 and Col. 2 lines 8-23).

27. **Claims 20-23** are rejected under 35 U.S.C. 103(a) as being unpatentable over Baddiley (US 4,852,065) in view of Anderson et al. (US 2004/0111567) as applied to **claim 1** above, and further in view of Glover (US 5,581,773).

28. Consider **claim 20**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, but does not discuss the use of a mask register, however Glover does disclose the claimed features of: a first masking register (44) arranged to mask bits of the data to be read out of the matrix of memory cells via a bit port of the memory (Col. 4 lines 11-14 and 65-67 and Col. 10 lines 57-62).

It would have been obvious to one of ordinary skill in the art at the time of the invention to include the teachings of Glover with that of Baddiley in view of Anderson et al., because Glover teaches that using the PE's and register's in the manner discloses can exclude the need for special corner turning hardware and allow for more PE's per chip therefore yielding significantly greater implementation economies and reduce cost and complexity (Col. 1 lines 43-55 and Col. 2 lines 37-67).

29. Consider **claim 21**, Baddiley in view of Anderson et al. discloses a memory according to **Claim 1**, but does not discuss the use of a mask register, however Glover

does disclose the claimed features of: a second masking register (46) arranged to mask bits of the data to be input to the matrix of memory cells via a bit port of the memory (Col. 4 lines 11-14 and 65-67 and Col. 10 lines 57-62).

It would have been obvious to one of ordinary skill in the art at the time of the invention to include the teachings of Glover with that of Baddiley in view of Anderson et al., because Glover teaches that using the PE's and register's in the manner disclosed can exclude the need for special corner turning hardware and allow for more PE's per chip therefore yielding significantly greater implementation economies and reduce cost and complexity (Col. 1 lines 43-55 and Col. 2 lines 37-67).

30. Consider **claim 22**, Baddiley disclose a multi-ported orthogonal data memory for effecting a data corner-turning function between a plurality of processors and location addressable data store, the memory being arranged to transfer **input data words** comprising a plurality of data items across a word port for the data store and transfer data bits **comprising an output word** across a bit port for the processors (fig. 2, abstract, Col. 1 lines 4-30 and Col. 3 lines 20-50, where a data item is considered to be a data word or some portion of a data word.), the memory comprising: a plurality of data memory cells arranged in the form of a matrix having rows and columns, and a plurality of groups of memory cells within the matrix, wherein each group: **i) a subgroup of the total number of memory cells in the matrix, ii) having members of the group located in different rows and in different columns of the matrix, iii) relates to a different size of data item and iv) is individually addressable to effect transfer of a data word thereto** (fig. 2, Col. 3 lines 20-58 and Col. 5 lines 1-10, where a group of memory

cells can be each buffer 20 and 21 themselves or a subset of a buffer that spans multiple rows and columns and the word data that is stored in each buffer and thus each group can be used to handle words of 32-bit size or smaller based on preset values and therefore each group is related to data items of a different size.); and enabling means having dedicated strobe connections to each of the plurality of groups of memory cells, and being arranged to enable selected ones of the plurality of groups of memory cells, as determined by the size of the data items being transferred, to transfer **all of the data items of the input data word** via the word port **into the selected group** or bit data **representing an output data word stored in the selected group** via the bit port in a single transfer operation (Fig. 2 and 3, Col. 3 lines 20-58 and Col. 5 lines 1-10, where each buffer is selected after a determination of the size of the data items is made and the arrangement of the data in the buffer is effected by the word size. Each buffer has dedicated connections for reading out and writing in data as shown in fig. 2 and 3 and a write or read operation is considered a single transfer operation.).

Baddiley uses an array of processing elements, but does not explicitly disclose whether these processing elements are SIMD processors, however Glover does teach the use of an array of processing elements just like in Baddiley that utilize SIMD processors (Col. 1 lines 13-55 and Col. 2 lines 28-42)

It would have been obvious to one of ordinary skill in the art at the time of the invention to include the teachings of Glover with that of Baddiley, because Glover teaches that SIMD processors are frequently used to process image data, just as the

processor array in Baddiley is designed to do, therefore being a common and well-known (Col. 1 lines 41-43).

Baddiley does not explicitly disclose that the claimed single transfer operation occurs in a **single clock cycle**. But Anderson et al. does teach that it is conventional for a multi-port memory devices to be able to read and write data in a single clock cycle (pg. 1 ¶ [0010]) and further that the improved multiport-memory of Anderson can also perform read and write access operations in one clock cycle, this improved multiport-memory can provide a significant reduction in chip area for a given memory storage capacity.

It would have been obvious to one of ordinary skill in the art at the time of the invention for the multi-ported memory of Baddiley to be able to perform read and write operations in one clock cycle, because Anderson et al. teaches that conventional multi-port memories can perform read and write accesses to data in one clock cycle (pg. 1 ¶ [0010]) and further because the improved multiport-memory of Anderson can also perform read and write access operations in one clock cycle, this improved multiport-memory can provide a significant reduction in chip area for a given memory storage capacity (pg. 1 ¶'s [0010] and [0011]).

Consider **claim 23**, as applied to **claim 1** above, Baddiley in view of Anderson et al. uses an array of processing elements, but does not explicitly disclose whether these processing elements are SIMD processors, however Glover does teach the use of an array of processing elements just like in Baddiley that utilize SIMD processors (Col. 1 lines 13-55 and Col. 2 lines 28-42)

It would have been obvious to one of ordinary skill in the art at the time of the invention to include the teachings of Glover with that of Baddiley in view of Anderson et al., because Glover teaches that SIMD processors are frequently used to process image data, just as the processor array in Baddiley is designed to do, therefore being a common and well-known (Col. 1 lines 41-43).

Response to Arguments

31. Applicant's arguments filed 3/25/2011 have been fully considered but they are not persuasive.

32. The Applicant first argues that the present **claim 1**, in contrast to Baddiley, requires members of the group to be located in different rows and in different columns of the matrix. As can be seen from the description of Baddiley at col. 3, lines 53-58, the data in Baddiley is stored only in a single row. However this is not the case in Baddiley, the new claim language merely requires there to be a matrix of cells and for cells in the matrix to be grouped into subgroups of the total number of cells in the matrix and that these cells in the group are located in different rows and columns. Baddiley clearly discloses memory devices with 8 rows and columns with 8 bit positions in each row and column and thus a group of cells can span multiple rows and columns and when using a 32-bit word format, the word will be stored in 4 rows and 8 columns and thus a data word is stored in multiple rows and columns although the claim language only requires the group to span different rows and columns not the word data itself.

33. The argument pertaining to a single transfer operation occurring in a single clock cycle has been addressed by the introduction of the Anderson et al. reference. Anderson et al. discusses that conventional multi-port memory devices can have read and write accesses that can be performed in one clock cycle and also that the multi-port memory used in the inventive concepts of Anderson et al. can perform read and write accesses in one clock cycle.
34. The Applicant finally argues that Baddiley does not teach, disclose, or suggest enabling means that enable selected ones of the plurality of groups of memory cells, as determined by the size of the data items being transferred. However Baddiley disclosing being able to have data words of multiple sizes and words of different sizes will take up less space than 32 bit words and thus take up a smaller amount of rows in the 8 by 8 bit memory array. Therefore the memory group selected to read out the data is partially determined by the word size.

Conclusion

Any inquiry concerning this communication or earlier communications from the examiner should be directed to MICHAEL ALSIP whose telephone number is (571)270-1182. The examiner can normally be reached on Monday through Thursday 9:00AM to 4:00PM.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Matt Kim can be reached on 571-272-4182. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see <http://pair-direct.uspto.gov>. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.
